Black box testing is a software testing technique that tests the functionality of a system without knowledge of its internal structure or implementation. It is also known as functional testing or end-user testing. In this type of testing, the tester interacts with the system as an end user would, without knowing the internal workings of the system. The tester only knows the inputs and outputs of the system, and the expected behavior of the system. Black box testing is used to verify that the system meets the requirements and behaves as expected from the user's perspective. It is a common testing technique for software development, and it is often used in conjunction with other testing techniques such as white box testing and gray box testing.
